1. SUMMARY

Public health priority
Urgent.

Case management
No known effective treatment. Isolate case with standard and contact precautions for the duration of illness. Determine the source of infection.

Contact management
Urgently assess the need for post-exposure prophylaxis in people exposed to mammalian animals or confirmed human cases. Use of human rabies immunoglobulin (HRIG) and rabies vaccine is dependent on the type of exposure and prior vaccination.

2. THE DISEASE

Infectious agents
Rabies virus, Australian bat lyssavirus (ABLV), and other lyssaviruses such as European bat lyssavirus (EBLV) 1 and EBLV 2, are members of the Rhabdoviridae family, genus Lyssavirus. Twelve (12) closely related but distinct lyssavirus species have been formally recognised. Rabies virus and other lyssaviruses cause the disease rabies.

Reservoir
All mammals are susceptible to infection with rabies virus and are therefore possible reservoirs. Dogs are the principal reservoir of rabies virus in developing countries and are responsible for 99% of human infections. Other reservoirs and important vectors of rabies virus include wild and domestic Canidae, including dogs, foxes, coyotes, wolves and jackals; and bats, cats, monkeys, skunks, raccoons, and mongooses. Other mammals may rarely be infected. Australia is currently free of rabies in terrestrial (land dwelling) mammals. However, evidence of ABLV infection has been documented in several species of flying foxes (also known as fruit bats) and insectivorous microbats. It is assumed that all Australian bat species have the potential to carry and transmit ABLV. ABLV has not been isolated from bats outside Australia. However, several lyssavirus species have been found in bats in other countries considered free of terrestrial rabies. It is assumed that bats anywhere in the world have the potential to carry and transmit lyssaviruses.

Mode of transmission
Rabies virus is transmitted by the virus-laden saliva of an infected animal introduced via a bite or scratch, or by contamination of mucous membranes or broken skin. Person-to-person transmission via saliva is extremely rare and has not been well documented.

There have been rare reports of rabies virus transmission by transplantation of infected tissues/ organs and via inhalation of virus-laden aerosol in laboratory settings. Aerosol transmission in humans has not been proven in the natural environment but based on animal experiments it remains theoretically possible.

The only three known human cases of ABLV infection occurred in people who had been bitten or scratched by bats. It is assumed that the mode of transmission for ABLV and other lyssaviruses is similar to that of rabies virus.
Incubation period

The incubation period for rabies virus infection is usually 3-8 weeks, rarely as short as a few days or as long as several years. The length of the incubation period depends on many factors including wound severity, wound location in relation to nerve supply, proximity to the brain, size of inoculum of virus and the degree of protection provided by clothing and other host factors. The incubation period for ABLV and other lyssavirus infections is less certain but is assumed to be similar to rabies virus; the first two documented cases of ABLV infection had likely incubation periods of approximately 4 weeks and over 2 years, respectively. The likely incubation for the third case has not been confirmed.

Infectious period

The infectious period for rabies virus infection has been described reliably only in dogs, cats and ferrets, in which communicability usually commences 3-7 days before onset of clinical signs and persists throughout the course of the illness. The period of communicability of ABLV and other lyssaviruses is not known.

Clinical presentation and outcome

As the clinical disease caused by classical rabies virus and other lyssaviruses appears to be indistinguishable, the term ‘rabies’ refers to disease caused by any of the known lyssaviruses. Rabies is an almost invariably fatal, acute viral encephalomyelitis. Initial symptoms include fever and sensory changes (pain or paraesthesia) at the site of a preceding animal bite. Other reported prodromal symptoms include a sense of apprehension, headache and malaise. There are 2 clinical forms of rabies. Encephalitic or furious rabies presents in about two-thirds of cases, and is characterised by hyperactivity and aerophobia and/or hydrophobia followed by delirium with occasional convulsions. The second form, paralytic or dumb rabies, presents in about one-third of cases, with paralysis of limbs and respiratory muscles with sparing of consciousness. Phobic spasms may be absent in the paralytic form. Death from cardiac or respiratory failure occurs within a few days for furious rabies and within 1-2 weeks for the paralytic form of the disease.

People at increased risk of disease

The risk of infection after the bite of a rabid animal can range from less than 1% to over 80%, presumably related to the size of inoculum, severity of bite, nerve density in the area of the bite, proximity of the bite to the central nervous system, vaccination status and immunocompetence. People at increased risk of rabies are those whose occupational, volunteering, or recreational activities put them at increased risk of exposure, i.e. being bitten or scratched by animals in rabies-enzootic countries or by bats anywhere in the world. In Australia, therefore, risk is greatest in those who holiday or work in countries in which rabies is enzootic, and in those most likely to come into contact with bat species, including wildlife carers, wildlife officers, veterinarians and those who live in areas where bats are common.

Disease occurrence and public health significance

Australia is free from terrestrial rabies. Only two imported human cases have been reported in Australia in travellers returned from enzootic areas. Rabies virus is enzootic in Asia (including Southeast Asia where large numbers of Australians travel), Africa, North and South America and parts of Europe. Worldwide, it is estimated that rabies virus is responsible for more than 50,000 deaths per year, almost all in rural areas of Asia and Africa, with the highest incidence in children under 15 years. Rabies is estimated to have at least as much public health impact in tropical countries as dengue fever (when comparing disability-adjusted life years) and results in an estimated annual global financial burden of over US$ 1 billion. Most human deaths follow dog bites for which adequate post-exposure prophylaxis was not or could not be provided. Post-exposure prophylaxis initiated
at an early stage using rabies vaccine in combination with rabies immunoglobulin may be 100% effective in preventing death. In Australia, rabies is subject to quarantine controls under Commonwealth biosecurity legislation – currently the Quarantine Act 1908. The primary concern is the prevention of the introduction of rabies virus to local dog and wildlife populations.

ABLV is unique to Australia and was first identified in 1996 in an encephalitic black flying fox. Three human cases have subsequently been reported, in 1996, 1998 and 2013 with all three cases developing fatal encephalitis after being bitten or scratched by bats. To date, virological and/or serological evidence of ABLV infection has been found in all four species of flying foxes (megachiropterans) found in Australia, and at least seven genera of Australian insectivorous bats. Any Australian bat should be considered a potential carrier of the virus. The risk of human exposure to ABLV is related to the extent of human contact with Australian bats.

Four human deaths have been documented following bat exposures in Europe (in Ukraine, the Russian Federation, Finland and Scotland). All presented with clinical features of rabies. The causative viruses were identified as EBLV 1a, EBLV 2a, EBLV 2b, and one untyped lyssavirus.

3. ROUTINE PREVENTION ACTIVITIES

Pre-exposure vaccination

Pre-exposure vaccination with rabies vaccine is recommended for people whose occupation (including volunteer work) or recreational activities place them at increased risk of being bitten or scratched by bats, and, following a risk assessment, those who work in or travel to rabies-enzootic countries. (WHO maintain maps of rabies-enzootic areas: see www.who.int/rabies/en; The UK Health Protection Agency (HPA) maintains a list of terrestrial rabies risk by country: See www.hpa.org.uk/webw/HPAweb&HPAwebStandard/HPAweb_C/1259152458758).

Current recommendations for pre-exposure vaccination include: bat handlers, veterinarians, wildlife officers, and others who come into direct contact with bats; laboratory personnel working with live lyssaviruses; expatriates and travellers (following a risk assessment) who will be spending time in rabies-enzootic areas; and people working with mammals in rabies-enzootic areas.

Pre-exposure vaccination with rabies vaccine consists of 3 doses by intramuscular (IM)* injection; with the second dose 7 days after the first and the third dose 21-28 days after the first dose. Booster doses are not required for anyone who has received 3 or more previous IM doses of rabies vaccine, if their only exposure risk is travelling to or living in a rabies enzootic area. Booster doses may be required if there is an ongoing occupational (including volunteer work) exposure risk, on the basis that there may be increased likelihood of an inapparent exposure occurring. An algorithm outlining the approach to booster doses is provided at Appendix 1. Consult the current edition of The Australian Immunisation Handbook if further information on vaccine administration and booster doses are required.

As described in the Australian Immunisation Handbook, there are two rabies vaccine preparations available in Australia, one a human diploid cell vaccine (HDCV) and the other a purified chick embryo cell vaccine (PCECV). PCECV must be given by the IM route, but HDCV may be given by either the IM or subcutaneous (SC) route. For simplicity, all descriptions of administration of rabies vaccine in these Guidelines refer to the IM route.

It is strongly recommended that the IM route be used for pre-exposure vaccination in
Australia. Antibody titres at 14 days are lower and wane more rapidly after intradermal (ID) administration of rabies vaccine, and there may be a slower initial immune response following exposure to rabies virus.\textsuperscript{21,22} As rabies vaccines are not licensed for intradermal use in Australia, any use of this method is the practitioner’s own responsibility. If ID rabies pre-exposure vaccination is considered (using a dose of 1.1 mL on days 0, 7 and 28) it is essential that:

- it is given by those with not only expertise in, but also regular practice of, the ID technique
- it is not administered to anyone who is immunocompromised
- it is not administered to those taking either chloroquine or other antimalarials structurally related to chloroquine (e.g. mefloquine) at either the time of, or within a month following, vaccination
- any remaining vaccine is discarded at the end of the session during which the vial is opened (i.e. within 8 hours)
- the rabies virus neutralising antibody (VNAb) level is checked 14 to 21 days following completion of the pre-exposure course of ID vaccine.
- It is only used for pre-exposure vaccination for classical rabies exposures (there are no data on the protection provided by ID rabies vaccination for the prevention of infection with other lyssaviruses including ABLV).\textsuperscript{20}

**Handling bats**

Only appropriately vaccinated and trained people should handle bats. Community members should not handle bats and should contact the nearest registered vaccinated wildlife carer (through a wildlife service or carer group), wildlife officer or veterinarian for assistance if a bat requires rescuing. If bats must be handled, safety precautions, such as wearing protective gloves and clothing, should be observed. Every effort should be made to avoid being bitten or scratched.

**Travel advice**

Travellers should be advised to avoid close contact with bats anywhere in the world. Travellers to rabies-endemic regions should also be advised to avoid close contact with wild or domestic terrestrial mammals (especially dogs, cats and monkeys). Travellers should also be advised what to do should they be bitten or scratched by an animal while abroad. This advice should include stressing the importance of obtaining as much written detail as possible on any post-exposure management provided overseas. Parents should ensure that their children are careful around animals as children are at optimal height for high-risk bites to the face and head. Rabies pre-exposure vaccination (or if appropriate, booster doses) should be advised pre-travel where indicated by a risk assessment, which should include ease of access to post-exposure prophylaxis (PEP) and likelihood of interaction with animals based on type of accommodation and planned activities.

**Management of potential human exposure to rabies or other lyssaviruses, including ABLV** (see algorithms in Appendices 2-3).
Definition of potential exposure

Any bite or scratch from, or mucous membrane or broken skin contact with the saliva or neural tissues of, a bat in Australia or elsewhere in the world, or a wild or domestic terrestrial mammal in a rabies-enzootic country. The latter includes Bali, Indonesia from August 2008 onwards.

If there are concerns about other potential exposures, expert advice should be sought.

Principles of post-exposure management

Post-exposure management is recommended for any person with a potential exposure. Post-exposure management comprises wound care and administration of a combination of rabies vaccine and human rabies immunoglobulin (HRIG), depending on exposure category and prior vaccination or antibody status. Post-exposure management should generally commence as soon as possible following potential exposure. If a traveller presents more than 10 days after being bitten or scratched by a domestic dog, cat or ferret in a rabies-enzootic country, and it can be reliably ascertained that the animal remains healthy, then post-exposure management is not required. Note that this recommendation does not apply to exposures to other animals, including bats, that may be documented to be alive beyond 10 days after the exposure.

Bats involved in a potential ABLV exposure in Australia should be tested where possible, without placing others at risk of exposure. In such situations PEP can be delayed for 48 hours post-exposure to enable a result from the bat to be received. If results are not likely to be available within 48 hours of exposure then PEP should be commenced. If the bat tests negative, PEP is not required, and may be discontinued if already commenced.

Wound care

Immediate cleansing of the wound is an important measure for minimising transmission risk. Animal studies have shown that immediate and thorough cleansing of the wound reduces the risk of infection. All wounds should be washed thoroughly for approximately 5 minutes with soap and copious water, as soon as possible after the exposure. A virucidal antiseptic solution such as povidone-iodine or alcohol should be applied. The wound should not be sutured unless unavoidable, and then should only occur after HRIG administration, where indicated. Consideration should also be given to the possibility of tetanus and other wound infections, and appropriate measures taken.

Lyssavirus exposure categories, to be used in conjunction with algorithms in Appendices 2-3

Source: Modified from WHO 2010

Post-exposure prophylaxis for people not previously vaccinated

Potential rabies virus and other lyssavirus (including ABLV) exposures

Immunocompetent people should receive 4 doses of rabies vaccine by IM injection on days 0, 3, 7 and 14. Where applicable, a single dose of HRIG should also be given as outlined in Appendices 2-3.
**Immunosuppression**

Immunocompromised people (whether through disease or treatment) should receive five doses of vaccine IM on days 0, 3, 7, 14 and 28, for both rabies and other lyssavirus (including ABLV) potential exposures. Where applicable, a single dose of HRIG should also be given, as outlined in Appendices 2-3. A person who is immune-suppressed should have rabies virus neutralising antibody (VNAb) titre checked 2 to 3 weeks after completion of the vaccine regimen. If the titre is <0.5 IU/ml a further dose of vaccine should be given and serology re-checked 2 to 3 weeks later. Where the titre remains suboptimal (<0.5 IU/mL) an infectious diseases expert should be consulted about the need for further doses.

**Post-exposure prophylaxis for people previously vaccinated**

People who have documented evidence of a completed IM course of pre-exposure prophylaxis or PEP using an appropriate cell culture based rabies vaccine at any time in the past, or who have documented rabies VNAb titres ≥0.5 IU/mL\(^{13}\) (e.g. at any time subsequent to a course of ID pre-exposure vaccination), should receive 2 doses of vaccine IM on days 0 and 3. HRIG is not required. If vaccination status is uncertain, management should occur as for people not previously vaccinated.

**Immunosuppression**

Previously vaccinated people who are immunocompromised (whether through disease or treatment) should have rabies virus neutralising antibody (VNAb) titre checked 2 to 3 weeks after the second dose of vaccine. If the titre is <0.5 IU/ml an infectious diseases expert should be consulted about the total number of doses required for PEP.

**Rabies vaccine use**

For adults and children one year of age or older, the rabies vaccine should be administered into the deltoid area, as administration in other sites may result in reduced neutralising antibody titres. In infants under 12 months of age, administration into the anterolateral aspect of the thigh is recommended.

**HRIG use**

HRIG, where indicated, should be infiltrated at a dose of 20 IU/kg in and around all wounds. It is imperative that as much HRIG as possible is given in and around the wound/s. It may be diluted if there are multiple wounds but as much as possible should go into and around the wounds. The balance of any HRIG dose that cannot safely be infiltrated in and around the wound, or the whole HRIG dose in situations such as mucous membrane exposures (where there is no wound), should be given IM (not into fat) at a site distant (e.g. alternative deltoid, lateral thigh, or glutal muscle, depending on volume) to that where rabies vaccine is given.

HRIG is given to provide localised anti-rabies antibody protection while the person mounts an immune response to the rabies vaccine. HRIG should be administered with the first dose of rabies vaccine (day 0). If this is not possible, HRIG can be given up to day 7 following the first dose of vaccine, but it is not recommended from day 8 onwards as it may suppress the immune response to the vaccine.

**Management of PEP in people who have begun prophylaxis overseas**

The principle of management of PEP in people who have begun prophylaxis overseas is to continue the course if treatment was commenced overseas with an appropriate cell culture derived vaccine. International advisory groups state that cell culture based vaccines can be used interchangeably to complete a treatment course.\(^{20}\) HRIG should be given if indicated, as outlined in Appendices 2-3, if RIG (whether equine or human) was not given and the person presents up to day 7 following the first vaccine dose. If the person presents from day 8 onwards then HRIG should not be administered.
A number of WHO endorsed rabies PEP schedules are used overseas. These include:
- Zagreb schedule (2 doses on day 0, single doses on days 7 and 21).
- Essen schedule (doses given on days 0, 3, 7, 14 and either 28 or 30).
- Modified Essen schedule (doses given on days 0, 3, 7 and 14).

The following table provides recommended courses of action for continuation of PEP in Australia after it has been commenced overseas, for the scenarios most commonly encountered. Other situations should be dealt with on a case by case basis, informed by the following considerations:
- HRIG should not be administered if Day 8 or later following the first documented dose of rabies vaccine, even if recommencing an interrupted vaccine course, on the basis that HRIG may suppress the immune response to rabies vaccine.
- Where there is good documentation that one or more doses of an appropriate cell culture based vaccine + RIG (equine or human) have been given, the schedule can generally be continued, with appropriate realignment.

In situations which are not straightforward, seek expert advice on an appropriate schedule, including consideration as to whether testing of rabies VNAb titres is indicated.

<table>

<th>Use of HRIG in Australia (Category III terrestrial animal exposures and Category II and III bat exposures only*)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unsure/unknown/poor documentation</td>
<td>Recomence course, starting from day 0</td>
<td>Administer HRIG if up to day 7 following the first dose of rabies vaccine. Do not administer if day 8 or later.</td>
</tr>
<tr>
<td>Well documented, RIG (equine or human) given, plus vaccine given either IM or ID</td>
<td>Align with nearest due dose and resume schedule, adjusting for delay and administering vaccine IM (e.g. if a person had only day 0 vaccine dose + RIG overseas, and presents 6 days later, give day 3 dose immediately, day 7 dose 4 days later and day 14 dose 7 days after that).</td>
<td>No HRIG needed</td>
</tr>
<tr>
<td>2 doses of rabies vaccine given IM on day 0, irrespective of whether RIG (equine or human) administered at same time as the 1st doses</td>
<td>Give further 2 doses, the first dose on day 7 and the 2nd dose on day 14. If patient presents after day 7, consider that day as day 7.</td>
<td>Administer HRIG if no RIG already given and if up to day 7 following the first doses of rabies vaccine. Do not administer if day 8 or later.</td>
</tr>
<tr>
<td>Immune impaired, with vaccine administered ID.</td>
<td>Irrespective of number of doses administer a 5-dose schedule IM and check antibody titre (see ‘Immunosuppression’ p7).</td>
<td>Administer HRIG if no RIG already given and if up to day 7 following the first ID dose of rabies vaccine administered overseas. Do not administer if day 8 or later.</td>
</tr>
<tr>
<td>Nerve tissue vaccine (NTV)</td>
<td>Recomence course, starting from day 0</td>
<td>Administer HRIG if no RIG already given, and if up to day 7 following first dose of NTV given overseas.</td>
</tr>
</tbody>
</table>

IM = intramuscular; ID = intradermal
* See Table ‘Lyssavirus exposure categories’ above and Appendices 2-3 below.
HRIG prioritisation in periods of shortage

Recurrent shortages of HRIG have occurred in Australia. From time to time, HRIG prioritisation measures may be implemented, at the recommendation of the Communicable Diseases Network Australia. These measures could include:

- Rounding down the dose when 0.5ml or less of a new ampoule is indicated to be injected in adults over 60kgs (e.g. 8.5 ml becomes 8 ml, requiring the use of four rather than five 2 ml ampoules of HRIG).
- Restricting the use of HRIG to potential exposures that have occurred within the last year only.
- Restricting the use of HRIG when there is an animal scratch but no bite, unless the scratch is on the head or neck, or the person is immunocompromised, or a higher risk of the animal involved being infected with rabies or another lyssavirus (including ABLV) is indicated.

4. SURVEILLANCE OBJECTIVES

- To rapidly identify people potentially exposed to rabies virus or other lyssaviruses (including ABLV) and to provide appropriate advice and prophylaxis.
- To monitor the epidemiology of rabies virus and other lyssavirus (including ABLV) infection and potential exposures to better inform prevention strategies, including travel advice.

5. DATA MANAGEMENT

- Only confirmed cases of rabies virus or other lyssavirus (including ABLV) infection should be reported. Data should be entered within one working day of notification.
- Data on potential human exposures and usage of HRIG and rabies vaccine should be collected and reported. De-identified data on potential exposures and vaccine/HRIG use is entered on the national database maintained by the Commonwealth Department of Health and Ageing see: www.outbreak.health.gov.au (log in permission provided by DoHA).

6. COMMUNICATIONS

Immediately report any suspected or confirmed case of rabies virus or other lyssavirus (including ABLV) infection by telephone to the state/territory Communicable Diseases Branch. Include information on the possible source/s of infection, other people thought to be at risk and any PEP recommendations. If local transmission of rabies virus is suspected the appropriate state or territory veterinary authority should be contacted urgently or phone the national Emergency Animal Disease Watch Hotline on 1800 675 888 (answered locally in each jurisdiction).

7. CASE DEFINITION

Only confirmed cases of rabies virus or other lyssavirus (including ABLV) infection are notifiable. The current surveillance case definition can be found at: http://www.health.gov.au/casedefinitions.

8. LABORATORY TESTING

Testing guidelines – humans

Testing for rabies virus or other lyssaviruses is indicated for persons where rabies is being considered in the differential diagnosis of a clinically compatible illness. Routine serological tests and antigen detection tests cannot distinguish between the different lyssaviruses, but they can be identified by PCR and culture. No laboratory tests are currently available to
diagnose rabies in humans before the onset of clinical disease. In the early stages of disease, saliva and CSF can be tested by virus culture and PCR. Antibody testing can also be performed on CSF. A positive serum antibody test is diagnostic of infection with a lyssavirus provided the person has never been immunised against rabies and may assist in the diagnosis of rabies in advanced clinical disease. Any negative test on a symptomatic person is not definitive, as viral shedding in body secretions is intermittent and early tests may be negative for antibody. Therefore repeat testing is often indicated. Post mortem, the standard diagnostic techniques include positive fluorescent antibody test (FAT) and PCR on fresh brain smears, and PCR and culture from tissues. Further information is available from the Public Health Laboratory Network (PHLN) case definition website: www.health.gov.au/internet/main/publishing.nsf/Content/laboratory-case-definitions-1

Refer to The Australian Immunisation Handbook for information on routine serological testing for immunity in people who may be occupationally exposed to rabies virus or other lyssaviruses (including ABLV) or who have impaired immunity.

**Testing and specimen submission guidelines – animals**

Testing of animals for rabies virus or other lyssaviruses (including ABLV) is indicated in any situation where a person has been exposed to a potentially infected animal. A positive result from FAT, virus culture or PCR on fresh brain smear of the animal is diagnostic of rabies. Where possible, PHU staff should arrange for safe handling, euthanasia where relevant and ABLV testing of bats that have been involved in potential human exposures. The process by which bats or bat specimens are to be transported to the appropriate reference laboratory should be documented in protocols within each state and territory. Before shipping specimens, submitters should contact the receiving laboratory to confirm arrangements e.g. for sampling, transport and specimen reception. Occasionally, implicated animals may be tested in overseas countries where Australians have been exposed – PHUs should endeavour to liaise with the overseas laboratory or public health authorities in such circumstances to ascertain the result.

**Reference laboratories**

The diagnosis of rabies due to rabies virus or ABLV can be confirmed in humans by Queensland Health Forensic and Scientific Services (QHFSS) and in animals by the Australian Animal Health Laboratory (AAHL). QHFSS and AAHL may also be able to test for other lyssaviruses. QHFSS and AAHL offer both nucleic acid testing and serology. A range of other animal and human health laboratories can perform serology and a small number can perform PCR for ABLV. Reference laboratories can provide advice on interpretation of test results.

9. CASE MANAGEMENT

Response times

On the same day of notification of a confirmed case of human disease begin follow up investigation and notify the state/territory Communicable Diseases Branch.

Response procedure

Case investigation

PHU staff conducting the investigation should ensure that action has been taken to:

a. confirm the onset date and symptoms of rabies
b. confirm results of laboratory tests
c. seek the doctor’s permission to contact the case (where possible) or relevant care-giver
d. interview case (if possible) or carer and determine source of infection - see Exposure Investigation.

Exposure Investigation

Determine the history of contact with bats (in Australia or overseas) or any other mammal in a rabies-enzootic country. Determine the type of animal (and for bats the species if possible), the circumstances and type of exposure, and whether other people or animals may also have been exposed.

Case treatment

There is no known effective treatment for rabies. A small number of cases of survival from rabies following intensive experimental and/or supportive treatment have been reported.\(^\text{26-28}\)

Education

The rabies factsheet should be available to carers, and provides information about the nature of infection and mode of transmission. See Appendix 5.

Isolation and restriction

Isolate patient with standard and contact precautions for the duration of the illness.

Active case finding

Active case finding should occur to determine if any other people or animals were exposed to the source animal of the case. Exposed people should be urgently assessed for post-exposure prophylaxis; exposed animals should be managed by veterinary authorities.

10. CONTROL OF ENVIRONMENT

Any suspected infected animals should be isolated from other animals and humans, and veterinary investigation/management sought. For overseas exposures to domestic dogs, cats or ferrets (but not other animals) where observation of the suspected animal is possible, information on whether the dog, cat or ferret remained healthy at least 10 days after the exposure incident may be useful for assessing risk of infection and the need for completion of PEP.\(^\text{29}\)

Environmental contamination by infected animals is considered negligible; this is based on knowledge of persistence of the classical rabies virus, which is fragile and does not survive for long outside the host.\(^\text{30}\) It is readily inactivated by heat and direct sunlight. Bats or other animals that have been dead for longer than 4 hours are no longer considered infectious for lyssaviruses.\(^\text{20}\) Bat or other animal blood, urine, and faeces are not considered to be infectious.\(^\text{20}\)
11. CONTACT MANAGEMENT

Identification of contacts

Contact tracing is required to provide advice and post-exposure prophylaxis so as to prevent disease in contacts.

Contact definition

Contacts are defined as

1. Persons who have been exposed to the saliva or neural tissue of an infectious person through mucous membrane or broken skin contact, or

2. Persons who have had mucous membrane or broken skin contact with potentially infected animals. This includes any bat in Australia or overseas, and any wild or domestic mammal in a rabies-enzootic country.

Prophylaxis

Post-exposure prophylaxis is recommended for persons who fit the contact definition above. See Management of potential human exposure to rabies or other lyssaviruses, including ABLV, and follow up using Rabies virus and other lyssavirus post-exposure prophylaxis form (see example in Appendix 4).

Education

The rabies factsheet should be available to inform exposed contacts about the nature of infection and mode of transmission. See Appendix 5.

Isolation and restriction

None required.

12. SPECIAL SITUATIONS

Domestic animal exposed to a bat in Australia

There is currently no evidence that wild or domestic mammals in Australia, other than bats, have ever naturally contracted ABLV infection, and no evidence that ABLV has ever been passed from a wild (non-bat) or domestic animal to a human. There is, however, a theoretical possibility that transmission to domestic animals could occur occasionally, and a theoretical (although even more remote) possibility that a domestic animal so infected could transmit infection to a human.

Follow-up by PHUs of incidents involving domestic animals which have suffered bites or scratches from bats is not required routinely. PHUs should, however, provide advice in accordance with this guideline if contacted by concerned owners. If the owners are concerned about the health of the domestic animal they should be referred to the relevant state or territory animal health authority. The AUSVETPLAN 2009 disease strategy for ABLV recommends testing of the bat involved in an exposure to a domestic animal. Unless the bat is proven to be negative, veterinarians are advised to take one of three options in regards to the animal: vaccinate; observe under formal or informal quarantine; or euthanase.
If a domestic animal which has been bitten or scratched by a bat subsequently bites or scratches a human, an expert panel may be convened to advise on management, at the discretion of the managing public health officer. If post-exposure prophylaxis is to be offered to human contacts in any situation involving domestic animals which have suffered bites or scratches from bats, in the absence of a defined human exposure (i.e., bite, scratch or mucous membrane exposure) to the bat, an expert panel should always be convened beforehand.

15. JURISDICTION SPECIFIC ISSUES

Information on State and Territory Public Health Legislation, the Quarantine Act 1908 and the National Health Security Act 2007:
Vaccine booster dose algorithm for protection against rabies virus or other lyssaviruses

Rabies or bay lyssavirus (including ABLV) booster algorithm

Ongoing occupational exposure risk
Perform serology
(i) Every 6 months for laboratory staff at risk.
(ii) Every 2 years for veterinary workers, bat handlers or any other workers who are likely to need to handle bats

Viral neutralising antibodies (VNAb) <0.5 IU/mL
Give a single booster dose

VNAb ≥0.5 IU/mL
No further action until either
- Further exposure then give PEP as per rabies or bat lyssavirus post-exposure algorithms
- Time period elapses as above for serology — undertake VNAb serology

If further exposure give PEP as per rabies or bat lyssavirus post-exposure algorithms

*NB. Immunocompromised patients’ serology should be checked 14-21 days post booster dose and a further dose offered if the result remains <0.5 IU/mL

No Longer Applicable
Withdrawn June 2016
APPENDIX 2

Post-exposure management algorithm for potential exposure to rabies virus from terrestrial animal overseas

Potential exposure from a terrestrial animal in a rabies-enzootic area

Category I
- Touching or feeding animals, licks on intact skin.
- Exposure to blood, urine or faeces or to an animal that has been dead for >4 hours.

No prophylaxis is required if contact history is reliable

Category II
- Nibbling of uncovered skin, minor scratches or abrasions without bleeding.

Non-immune, ± immunocompetent
- Vaccinate§
  4 doses administered IM on days 0, 3, 7 and 14. Human rabies immunoglobulin (HRIG) is not indicated.

Previously Immunised†
- Both immunocompetent and immunocompromised persons — 2 doses delivered IM on days 0 and 3. HRIG is not indicated.

Non-immune, ± immunocompetent
- Vaccinate§
  Both immunocompetent and immunocompromised persons — 2 doses delivered IM on days 0 and 3. HRIG is not indicated.

If further exposures in the future
- Treat as previously immunised and follow algorithm as above

If ongoing occupational exposure risk — see Booster algorithm.

Category III
- Single or multiple transdermal bites or scratches.
- Contamination of mucous membrane with saliva from licks.
- Licks on broken skin.

Non-immune, ± immunocompetent
- Vaccinate§ and administer HRIG
  HRIG is administered only once, and as soon as possible after the initiation of PEP (HRIG is not indicated beyond the 7th day after the 1st vaccine dose day 0). Rabies vaccination is 4 doses

Immunocompromised persons, not previously vaccinated, should receive 5 doses of vaccine on days 0, 3, 7, 14 and 28. Serology should be checked 14-21 days post dose 5 and a further dose offered if the result is <0.5 IU/mL. In immunocompromised persons HRIG should be administered if a Category II and III exposure.

Immunocompromised persons, previously immunised, should have a serological testing 14-21 days after the 2nd dose to confirm acceptable VNAb levels. If the results is <0.5 IU/mL, expert advice should be sought regarding the total number of doses required for PEP.

* If in doubt, treat as non-immune.
† Previously Immunised — documentation of a completed recommended PreP or PEP rabies vaccine regimen. This is irrespective of the time period since the last dose was administered. This may either be a completed primary pre-exposure course or post-exposure course and includes those where subsequent boosting has occurred, or documented rabies antibody (VNAb) titres of ≥ 0.5 IU/mL.
± Non-immune — person who has never received pre- or post-exposure immunisation with rabies vaccine, has had incomplete/inadequate primary vaccination course, or if any doubts about the vaccine(s) administered overseas.

Guidelines for the Public Health Management of Rabies and Other Lyssavirus (including Australian Bat Lyssavirus) Exposures and Infections

APPENDIX 3

Post-exposure management algorithm for potential exposure to lyssaviruses from bats in Australia or overseas

Potential exposure from a bat (Australia or overseas)

**Category I**
- Touching or feeding animals, licks on intact skin.
- Exposure to blood, urine or faeces or to an animal that has been dead for >4 hours.

**Category II or III**
- Nibbling of uncovered skin, any scratches or abrasions with/without bleeding, single or multiple transdermal bites or scratches, contamination of mucous membrane with saliva from licks, or licks on broken skin.

**Previously immunised*** †

**Vaccinate§§**
Both immunocompetent and immunocompromised persons – 2 doses delivered IM on days 0 and 3. Human rabies immunoglobulin (HRIG) is not indicated.

**Non-immune, ± immunocompetent**

**Vaccinate§ and administer HRIG§**
HRIG is administered only once, and as soon as possible after the initiation of PEP (HRIG) is not indicated beyond the 7th day after the 1st vaccine dose (day 0). Rabies vaccination is 4 doses administered IM on days 0, 3, 7 and 14.

**Perform serology**
(i) Every 6 months for laboratory staff at risk.
(ii) Every 2 years for veterinary workers, bat handlers or any other workers who are likely to need to handle bats.

**VNAβ <0.5 IU/mL**
- Give a single booster dose
- If further exposure give PEP as above

**VNAβ ≥0.5 IU/mL**
- No further action until either
  - Exposure, then give PEP as above
  - Time period elapses as above for serology — undertake VNAβ serology

---

§ Immunocompromised persons, not previously vaccinated, should receive 5 doses of vaccine on days 0, 3, 7, 14 and 28. Serology should be checked 14-21 days post dose 5 and a further dose offered if the result is <0.5 IU/mL. In immunocompromised persons, HRIG should be administered if a Category II and III exposure.

§§ Immunocompromised persons, previously immunised, should have had a serological testing 14-21 days after the 2nd dose to confirm acceptable VNAβ levels. If the results is <0.5 IU/mL, expert advice should be sought regarding the total number of doses required for PEP.

* If in doubt, treat as non-immune.
† Previously immunised — documentation of a completed recommended PreP or PEP rabies vaccine regimen. This is irrespective of the time period since the last dose was administered. This may either be a completed primary pre-exposure course or post-exposure course and includes those where subsequent boosting has occurred, or documented rabies antibody (VNAβ) titres of ≥ 0.5 IU/mL.
± Non-immune — person who has never received pre- or post-exposure immunisation with rabies vaccine, has had incomplete/inadequate primary vaccination course, or if any doubts about the vaccine(s) administered overseas.

Australian bat lyssavirus FACT SHEET
Rabies virus and other lyssaviruses (including Australian bat lyssavirus)

What are rabies virus and other lyssaviruses such as Australian bat lyssavirus?
Rabies virus and Australian bat lyssavirus (ABL V) belong to a group of viruses called lyssaviruses. These viruses are usually transmitted via a bite from an infected ("rabid") animal. They all cause a similar illness known as rabies, which affects the central nervous system and is usually fatal. The World Health Organization estimates that more than 55,000 people die from rabies worldwide each year. Rabies virus does not currently occur in land dwelling animals in Australia. However, ABLV, which is closely related but not identical to rabies virus, does occur in Australia, and can be transmitted from bats to humans. Only three cases of human infection with ABLV have been recorded since the virus was first identified in 1996. All three cases were in Queensland and all died as a result of ABLV infection after being bitten or scratched by bats.

What are the symptoms?
The early symptoms of rabies are flu-like, including headache, fever and fatigue. The illness progresses rapidly to paralysis, delirium, convulsions and death, usually within a week or two of the onset of illness. There is a wide variability in the time it takes for symptoms to appear following exposure to an infected animal (from several days to several years).

How are they spread?
Rabies virus and other lyssaviruses (including ABLV) are spread from infected animals to people through bites or scratches, or by being exposed to infected animals’ saliva through the eyes, nose or mouth. Only mammals can be infected. Overseas, dogs are the main transmitter of rabies. Other animals that transmit rabies overseas include bats, monkeys, foxes, cats, raccoons, skunks, jackals and mongooses.

In Australia, evidence of ABLV infection has been found in various species of flying foxes/fruit bats and insect-eating microbats. It is assumed that any bat in Australia could potentially carry ABLV. The behaviour or appearance of a bat is not an accurate guide as to whether it is carrying the virus. Lyssaviruses are unlikely to survive outside a bat or other animal for more than a few hours, especially in dry environments that are exposed to sunlight. Contact or exposures to bat (or other animal) faeces, urine or blood do not pose a risk of exposure to lyssaviruses, and nor do living, playing or walking near bat roosting areas.

Who is at risk?
People who handle bats in Australia or overseas, and people who come into contact with wild or domestic land dwelling mammals in a country where there is a rabies virus risk, are at increased risk of rabies.

How is it prevented?
The best protection against being exposed to rabies or other lyssaviruses (including ABLV) is to avoid handling any bat in Australia or overseas, or any wild or domestic land dwelling mammal in...
a country where there is a rabies virus risk. This includes wild or domestic dogs, cats, and monkeys. Only people who have been vaccinated against rabies and who have been trained in the care of bats should ever handle bats or flying foxes. Anyone who comes across an injured bat should contact the relevant state government authority or a local wildlife care group or rescuer for assistance. Do not touch the bat and avoid direct contact with any bat saliva.

Rabies vaccine is used to protect against infection with rabies virus and other lyssaviruses (including ABLV). A course of three injections, given over one month, is recommended for people whose job or other activities place them at increased risk of being bitten or scratched by bats in Australia or overseas, or land dwelling mammals in countries where there is a rabies virus risk. Periodic booster doses of vaccine may also be required. If you intend to work in or travel to a country or countries where there is a rabies virus risk, you should discuss with your doctor whether you should be vaccinated. This will depend on the period of time you will be away, the risk of animal bites, and how easy it would be to access emergency medical attention if bitten or scratched.

If you are bitten or scratched by a bat anywhere in the world or by a land dwelling mammal overseas, you should:

- immediately wash the wound thoroughly with soap and water for at least five minutes - proper cleansing of the wound reduces the risk of infection
- apply an antiseptic with anti-virus action such as povidone-iodine, iodine tincture, aqueous iodine solution or alcohol (ethanol) after washing
- seek medical attention as soon as possible to care for the wound and to assess whether you are at risk of infection

If you are at risk of infection and have not been vaccinated previously, you will require an injection of rabies immunoglobulin as soon as possible and a series of either four or five rabies vaccine injections over one month. Even if you have been vaccinated before, you will require two further doses of vaccine. The relevant Australian state or territory health department will fund these vaccines and arrange for them to be delivered to your GP or hospital in Australia. Rabies immunoglobulin is often difficult to obtain in overseas countries but vaccine is usually available.

If the animal or bat can be tested without placing other people at risk of exposure, vaccination may be delayed for up to 48 hours. In Australia, testing of bats can be arranged by the local public health unit. If the bat does not have ABLV, the course of vaccinations will not be required, or can be ceased.

How is it diagnosed?
Diagnosis requires confirmation by laboratory tests for the presence of lyssaviruses in skin, blood, spinal fluid and nervous tissue.

How is it treated?
There is no available treatment for rabies once symptoms have started.

What is the public health response?
Doctors should contact their local public health unit for advice on people bitten or scratched by animals, including bats, that could transmit rabies or other lyssaviruses. Public health unit staff will help arrange vaccination following exposure and rabies immunoglobulin where required.
Hospitals and laboratories will notify cases of rabies to the local public health unit. Public health unit staff will investigate the likely source and determine whether others may be at risk of infection.

**Further information**

For further information, please contact your local doctor or nearest public health unit.

APPENDIX 7

PHU rabies virus and other lyssaviruses (including ABLV) follow-up checklist

Patient ID number:

1. If potential exposure to rabies or other lyssaviruses (including ABLV)

   **Contact the exposed person (or care-giver) to:**
   - Identify source and circumstances of potential exposure, including identification of bat species if possible.
   - Determine if any other persons or animals were exposed to same animal/bat.
   - Determine if animal/bat available for testing and arrange testing where appropriate.
   - Review exposed person’s vaccination status and immune competence, and discuss need for post-exposure treatment (PET) and prophylaxis (PEP) and if they have a preferred doctor to manage provision of PET.
   - Provide with Rabies Factsheet.

   **Contact exposed person’s doctor to:**
   - Discuss need for PET, including wound management and provision of PEP.
   - Complete Rabies virus and other lyssaviruses (including ABLV) post-exposure prophylaxis form.
   - Arrange for timely delivery of vaccine and HRIG to attending doctor, or other health care provider, as appropriate, by telephoning the **CSL Duty Officer:**

     **During Business Hours:**
     Tel: 9328 7322
     Fax: 9227 6196
     **After hours on call telephone number:** 0402 891 810
     **Or, if no answer, telephone on call pager:** 9483 6085

     In addition, fax a copy of the completed HRIG/HRV order form to **CSL 9227 6196** and a copy of both the order and the incident report form to the **Administration Officer, Communicable Disease Control Directorate (fax: 9388 4848).**

   **Contact laboratory to:**
   - Facilitate animal testing, where appropriate. In Australia, this may require liaison with jurisdictional animal health authorities to arrange handling and transport of the animal to a laboratory with capacity to test for lyssaviruses.

No Longer Applicable
Withdrawn June 2016
• To arrange the collection and delivery of the implicated bat(s) to the State Animal Health Laboratory for ABL testing (see Bat ABL Testing below).

• GPs should complete and fax the Australian Bat Lyssavirus Exposure Form (attached) to the relevant Public Health Physician or Medical Officer, Communicable Disease Control Directorate (fax: 9388 4848). A copy of the completed Form must be included with each bat that is transported to the State Animal Health Laboratories for ABL testing.

**BAT ABL TESTING**

Wherever possible, the implicated bat(s) should be captured and sent to the State Animal Health Laboratory, which will then send specimens to the Australian Animal Health Laboratories in Victoria for ABL testing.

• The Regional Public Health Unit will arrange and bear the costs of euthanasia and transport of the implicated bat(s) to the State Animal Health Laboratory.

• The State Animal Health Laboratory will provide instructions on how to capture and deliver the implicated bat. Business hours telephone: 9368 3351, (fax: 9474 1881). After hours, telephone the On-Call Veterinarian on 1800 675 888.

• If the bat is alive it should be secured appropriately for transport. If it is dead, or if it is more convenient to kill the bat for transport, it should be kept at 4°C (not frozen). Live bats will be euthanized for testing when they reach the laboratory.

• The bat container should be labelled ‘URGENT – Bat (Human Exposure)’ and couriered to: The Veterinary Virologist, Department of Agriculture and Food, Animal Health Laboratories Receivals (C Block), 3 Baron-Hay Court, SOUTH PERTH WA 6151.

**Other issues:**

• Inform local health care providers and the general public as appropriate about the incident and provide advice on how to minimise the risk of exposure to ABL infection.

• Report details of exposure, PET and animal testing to state/territory communicable diseases branch.

• Enter exposure data into NetEpi and/or jurisdictional database, as appropriate.

2. If rabies case

**Contact the patient’s doctor to:**

• Obtain patient’s history.
• Confirm results of relevant pathology tests.
• Recommend that the tests be done if need be.

**Contact the patient (or care-giver) to:**

• Confirm onset date and symptoms of the illness.
• Identify likely source of exposure including type of animal/bat and type of exposure.
• Determine if any other persons/animals were exposed to same animal/bat.
• Provide with Rabies Factsheet.

**Contact laboratory to:**
- Obtain any outstanding results.

**Confirm case**

- Assess information against case definition.

**Other issues:**

- Report details of case to state/territory communicable diseases branch and senior managers as appropriate. Telephone 9388 4868, after hours 9328 0553.
- Enter case data onto notifiable diseases database.
This document is available in different formats, upon request from a person with disability.
